

# Methods

specific piece of code which is use to call multiple time when needed instead of writing the whole code everytime.

## Syntax-

```
<access specifier> <modifier> <datatype> methodName(  
    list of parameter)  
{  
    // body  
}
```

- **modifier** - It defines the access type of the method & it is optional.
- **datatype** - method may return a value.
- **method Name** - It is name of method. The method signature consist of method name & the parameter list.
- **method body** - body defines what the method does.

Method Overloading - When a class has two or more methods by the same name but different parameters, it is known as method overloading.

Ex- `int max(int a, int b)`

`int float max(float a, float b)`

`int String max(String a, String b)`

Pass by Value - The method parameter values are copied to another variable & then the copied object is passed.

Pass by Reference - A reference to the actual parameter is passed to the method.

# Constructors

- Similar to Method
- No return type
- Obj Method name same as class name.
- Constructor invoked during object call.

Example-

```
class Prac {
    Prac()
    { // body
    }
}
```

Default Constructor - In this the default value of the used data type is assigned to the variable.

Parameterized Constructor - When value is assigned in constructor during function call.

```
class Drive {
    String v; // String Vehicle
    Drive(String vehicle)
    {
        v = vehicle; // this.vehicle = vehicle
    }
}
```

Default cons. can not be called if parameter is made.

22

```
public static void main (String args[])  
{  
    Drive obj = new Drive ("car");  
    System.out.println (obj.v);  
}  
}
```

Constructor Overloading - Two or more constructor different in parameter.

```
class Drive {  
    String vehicle;  
    int speed;
```

```
    Drive()  
    {  
        vehicle = "";  
        speed = 0;  
    }
```

```
    Drive (vehicle)  
    {  
        this.vehicle = vehicle;  
    }
```

```
    Drive (vehicle, speed)  
    {  
    }
```

The keyword `static` indicates that the particular member belongs to a type itself, rather than to an instance of that type. It is mainly used to help memory management.

The keyword can be applied to variables, methods, blocks and nested class.

\* Object creation of non-static inner class -

A objA = new A();  
B objB = objA.new B();

object of outer class is necessary for accessing inner-class.

\* Object creation of static inner class -

C objC = new A.C();

Static Block -

These are the piece/block of code in a program which executes before the main functions starts execution.

(सबसे पहले से चलना तब कुछ और होगा)

static {

---

---

}

These are written outside the main().
